```

In this lab, you'll use Pytorch to implement an RNN that performs a useful application, punctuation restoration.

New bits of Python used for the first time in the *solution set* for this lab, and which you may therefore find useful:

- `torch.clamp` : restricts all elements of a tensor to a specific range
- `torch.diag` : creates a tensor with the given inputs as the diagonal
- `torch.eye` : creates an identity matrix
- `torch.mv` (typically invoked via the `@` operator): matrix-vector multiplication
- `torch.prod` : takes the product of elements in a vector
- `torch.T` : returns the transpose of a tensor
- `torch.zeros` : creates a matrix of zeros

Preparation – Loading packages

In [ ]:

```
import sys
import torch
import wget
import math
import torch.nn as nn
import random
import csv

from datasets import load_dataset
from tokenizers import Tokenizer
```

```python
from tokenizers.models import WordLevel
from tokenizers.pre_tokenizers import WhitespaceSplit
from tokenizers.trainers import WordLevelTrainer
from transformers import PreTrainedTokenizerFast
from collections import Counter
from tqdm.notebook import tqdm
import copy
```

In [ ]:
```python
# Script for visualizing computation graphs
data_dir = "data/"
sys.path.append(data_dir)
os.makedirs(data_dir, exist_ok=True)

wget.download('https://raw.githubusercontent.com/nlp-course/data/master/scri
from makedot import make_dot

# Fix random seed for replicability
SEED=1234
random.seed(SEED)
torch.manual_seed(SEED)
```

In [ ]:
```python
## GPU check
device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
print(device)
```

Punctuation restoration as RNN sequence labeling

In this lab, you will use recurrent neural networks (RNNs) for sequence labeling.

We consider the task of *automatic punctuation restoration* from unpunctuated text, which is useful for post-processing transcribed speech from speech recognition systems (since we don't want users to have to utter all punctuation marks). We can formulate this task as a sequence labeling task, predicting for each word the punctuation that should follow. If there's no punctuation following the word, we use a special tag `O` for "other".

The dataset we use is the Federalist papers. We use text without punctuation as our input, and predict the punctuation following each word. An example constructed from the dataset looks like below, which correponds to the punctuated sentence `the powers to make treaties and to send and receive ambassadors , speak their own propriety .`

Token	Label
<bos>	O
the	O

Token	Label
powers	O
to	O
make	O
treaties	O
and	O
to	O
send	O
and	O
receive	O
ambassadors	,
speak	O
their	O
own	O
propriety	.

First, we load the data.

In [ ]:
```
# Prepare to download needed data
def download_if_needed(source, dest, filename):
    os.makedirs(data_path, exist_ok=True) # ensure destination
    os.path.exists(f"./{dest}{filename}") or wget.download(source + filename

source_path = "https://raw.githubusercontent.com/nlp-course/data/master/Fede
data_path = "data/"

# Download the files
for filename in ["federalist_tag.train.txt",
                 "federalist_tag.dev.txt",
                 "federalist_tag.test.txt"
                ]:
    download_if_needed(source_path, data_path, filename)

# Read in the dataset, extracting the token sequences and the
# corresponding tag sequences and generate a CSV file of the
# processed data
for split in ['train', 'dev', 'test']:
    in_file = f'data/federalist_tag.{split}.txt'
    out_file = f'data/federalist_tag.{split}.csv'

    with open(in_file, 'r') as f_in:
        with open(out_file, 'w') as f_out:
            text, tag = [], []
            writer = csv.writer(f_out)
            writer.writerow(('text','tag'))
```

```
                for line in f_in:
                    if line.strip() == '':
                        writer.writerow((' '.join(text), ' '.join(tag)))
                        text, tag = [], []
                    else:
                        token, label = line.split('\t')
                        text.append(token)
                        tag.append(label.strip())
```

Let's take a look at what each data file looks like.

In [ ]:
```
shell('head "data/federalist_tag.train.csv"')
```

We'll use the HuggingFace `datasets` package to further prepare the data.

In [ ]:
```
federalist_dataset = load_dataset('csv', data_files={'train':'data/federalis
                                                      'val': 'data/federalist
                                                      'test': 'data/federalis
federalist_dataset
```

In [ ]:
```
# Split out the training, validation, and test sets
train_data = federalist_dataset['train']
val_data = federalist_dataset['val']
test_data = federalist_dataset['test']
```

We build a tokenizer from the training data to tokenize text and convert tokens into word ids.

In [ ]:
```
# We place a limit on the size of the vocabulary, including only the
# `MAX_VOCAB_SIZE` most frequent words. All others will become `[UNK]`.
MAX_VOCAB_SIZE = 5000
unk_token = '[UNK]'
pad_token = '[PAD]'

text_tokenizer = Tokenizer(WordLevel(unk_token=unk_token))
text_tokenizer.pre_tokenizer = WhitespaceSplit()

trainer = WordLevelTrainer(vocab_size=MAX_VOCAB_SIZE, special_tokens=[pad_to
text_tokenizer.train_from_iterator(train_data['text'], trainer=trainer)
```

We use `datasets.Dataset.map` to convert text into word ids. As shown in lab 1-5, first we need to wrap `text_tokenizer` with the `transformers.PreTrainedTokenizerFast` class to be compatible with the `datasets` library.

In [ ]:
```
# Wrap the tokenizer to allow use with HF datasets
hf_text_tokenizer = PreTrainedTokenizerFast(tokenizer_object=text_tokenizer,
                                            pad_token=pad_token,
                                            unk_token=unk_token)

# encode(example) -- Updates the `example` by tokenizing and encoding the te
# into a list of token ids.
```

```python
def encode(example):
    return hf_text_tokenizer(example['text'])

# Encode the training, validation, and test sets
train_data = train_data.map(encode)
val_data = val_data.map(encode)
test_data = test_data.map(encode)
```

In [ ]:
```python
# An example from the training dataset, showing the string of tokens,
# the string of tags, and the list of token ids. The token type ids
# and attention mask can be ignored for the time being.
train_data[0]
```

We also need to convert the string of tags into a list of tag ids.

In [ ]:
```python
tag_tokenizer = Tokenizer(WordLevel())
tag_tokenizer.pre_tokenizer = WhitespaceSplit()

tag_trainer = WordLevelTrainer(special_tokens=[pad_token])
tag_tokenizer.train_from_iterator(train_data['tag'], trainer=tag_trainer)

hf_tag_tokenizer = PreTrainedTokenizerFast(tokenizer_object=tag_tokenizer, p

# encode_tag(example) -- Updates the `example` by tokenizing and encoding th
# into a list of tag ids.
def encode_tag(example):
    example['tag_ids'] = hf_tag_tokenizer(example['tag']).input_ids
    return example

train_data = train_data.map(encode_tag)
val_data = val_data.map(encode_tag)
test_data = test_data.map(encode_tag)
```

In [ ]:
```python
# An example from the training dataset, showing the string of tokens,
# the string of tags, and the list of token ids. The token type ids
# and attention mask can be ignored for the time being.
train_data[0]
```

In [ ]:
```python
# Print out some stats
text_vocab = hf_text_tokenizer.get_vocab()
tag_vocab = hf_tag_tokenizer.get_vocab()
vocab_size = len(text_vocab)
num_tags = len(tag_vocab)

most_common_tokens = Counter(token
                             for sentence in train_data['text']
                             for token in sentence.split()).most_common(10)
most_common_tags = Counter(tag
                           for sentence_tags in train_data['tag']
                           for tag in sentence_tags.split()).most_common(10)

print(f"Size of vocab: {vocab_size}")
print (f"Most common English words: {most_common_tokens}\n")
```

```
print(f"Number of tags: {num_tags}")
print (f"Most common tags: {most_common_tags}")
```

You can see from above that the most common punctuation is comma, on which we will evaluate precision, recall, and F-1 scores later.

We mapped words that are not among the most frequent words (specified by `MAX_VOCAB_SIZE`) to a special unknown token:

In [ ]:
```
unk_index = text_vocab[unk_token]

print (f"Unknown word: {unk_token}\n"
       f"Unknown index: {unk_index}")
```

To facilitate batching sentences of different lengths into the same tensor we also reserved a special padding symbol `[PAD]` for both `text_vocab` and `tag_vocab`.

In [ ]:
```
print (f"Padding token: {pad_token}")
text_pad_index = text_vocab[pad_token]
print (f"Padding text_vocab token id: {text_pad_index}")
tag_pad_index = tag_vocab[pad_token]
print (f"Padding tag_vocab token id: {tag_pad_index}")
```

To load data in batched tensors, we use `torch.utils.data.DataLoader` for data splits, which enables us to iterate over the dataset under a given `BATCH_SIZE`, which is set to be `1` throughout this lab. We still batch the data because other torch functions expect data to be batched.

In [ ]:
```
# We use batch size 1 for simplicity
BATCH_SIZE = 1

# collate(examples) -- Combines a list of examples into a single batch
def collate_fn(examples):
    batch = {}
    bsz = len(examples)
    input_ids, tag_ids = [], []
    for example in examples:
        input_ids.append(example['input_ids'])
        tag_ids.append(example['tag_ids'])

    max_length = max([len(word_ids) for word_ids in input_ids])

    tag_batch = torch.zeros(bsz, max_length).long().fill_(tag_vocab[pad_toke
    text_batch = torch.zeros(bsz, max_length).long().fill_(text_vocab[pad_to
    for b in range(bsz):
        text_batch[b][:len(input_ids[b])] = torch.LongTensor(input_ids[b]).t
        tag_batch[b][:len(tag_ids[b])] = torch.LongTensor(tag_ids[b]).to(dev

    batch['tag_ids'] = tag_batch
    batch['input_ids'] = text_batch
    return batch
```

```
train_iter = torch.utils.data.DataLoader(train_data,
                                         batch_size=BATCH_SIZE,
                                         shuffle=True,
                                         collate_fn=collate_fn)
val_iter = torch.utils.data.DataLoader(val_data,
                                       batch_size=BATCH_SIZE,
                                       shuffle=False,
                                       collate_fn=collate_fn)
test_iter = torch.utils.data.DataLoader(test_data,
                                        batch_size=BATCH_SIZE,
                                        shuffle=False,
                                        collate_fn=collate_fn)
```

Let's take a look at the dataset. Recall from project 1 that there are two different ways of iterating over the dataset, one by iterating over individual examples, the other by iterating over batches of examples.

In [ ]:
```
# Iterating over individual examples:
# Note that the words are the original words, so you'd need to manually
# replace them with `[UNK]` if not in the vocabulary.
example = train_data[1]

text = example["text"].split()  # a sequence of unpunctuated words
tags = example["tag"].split()   # a sequence of tags indicating the proper p

print(f'{"TYPE":15}: {"TAG"}')
for word, tag in zip(text, tags):
    print(f"{word:15}: {tag}")
```

Alternatively, we can produce the data a batch at a time, as in the example below. Note the "shape" of a batch; it's a two-dimensional tensor of size `batch_size x max_length`. (In this case, `batch_size` is 1.) Thus, to extract a sentence from a batch, we need to index by the *first* dimension.

In [ ]:
```
# Iterating over batches of examples:
#
# Note that the collat_fn returns input_ids and tag_ids only, so you
# need to manually convert them back to strings.
# Unknown words have been mapped to unknown word ids

batch = next(iter(train_iter))
text_ids = batch['input_ids']
example_text = text_ids[0]
print (f"Size of first text batch: {text_ids.size()}")
print (f"First sentence in batch: {example_text}")
print (f"Mapped back to string: {hf_text_tokenizer.decode(example_text)}")

print ('-'*20)

tag_ids = batch['tag_ids']
example_tags = tag_ids[0]
print (f"Size of tag batch: {tag_ids.size()}")
```

```
print (f"First sentence in batch: {example_tags}")
print (f"Mapped back to string: {hf_tag_tokenizer.decode(example_tags, clear
```

Given the tokenized tags of an unpunctuated sequence of words, we can easily restore the punctuation:

In [ ]:
```
def restore_punctuation(word_ids, tag_ids):
    words = hf_text_tokenizer.convert_ids_to_tokens(word_ids)
    tags = hf_tag_tokenizer.convert_ids_to_tokens(tag_ids)
    words_with_punc = []
    for word, tag in zip(words, tags):
        words_with_punc.append(word)
        if tag != "O":
            words_with_punc.append(tag)
    return " ".join(words_with_punc)
```

In [ ]:
```
print(restore_punctuation(example['input_ids'], example['tag_ids']))
```

Majority Labeling

We start by implementing a simple baseline without RNNs.

A naive baseline is choosing the majority label for each word in the sequence, where the majority label depends on the word. We've provided an implementation of this baseline for you, to give you a sense of how difficult the punctuation restoration task is.

In [ ]:
```
class MajorityTagger:
    def __init__(self):
        """Initializer"""
        self.most_common_label_given_word = {}

    def train_all(self, train_iter):
        """Finds the majority label for each word in the training set"""
        train_counts_given_word = {}
        for batch in train_iter:
            for example_input_ids, example_tag_ids in zip(
                batch["input_ids"], batch["tag_ids"]
            ):
                for word_id, tag_id in zip(example_input_ids, example_tag_ic
                    if word_id not in train_counts_given_word:
                        train_counts_given_word[word_id.item()] = Counter([]
                    train_counts_given_word[word_id.item()].update([tag_id.i

        for word_id in train_counts_given_word:
            self.most_common_label_given_word[word_id] = train_counts_given_
                word_id
            ].most_common(1)[0][0]

    def predict_all(self, test_iter):
        """Predicts labels for each example in test_iter

        Returns a list of list of strings. The order should be the same as
```

```
        in `test_iter.dataset` (or equivalently `test_iter`).
        """
        predictions = []
        for batch in test_iter:
            batch_predictions = []
            for example_input_ids in batch["input_ids"]:
                example_tag_ids_pred = []
                for word_id in example_input_ids:
                    tag_id_pred = self.most_common_label_given_word[word_id.
                    example_tag_ids_pred.append(tag_id_pred)
                batch_predictions.append(example_tag_ids_pred)
            predictions.append(batch_predictions)
        return predictions  # batch list -> example list -> tag list

    def evaluate(self, test_iter):
        """Returns the overall accuracy of comma predictions, and the
        precision, recall, and F1
        """
        correct = 0
        total = 0
        true_positive_comma = 0
        predicted_positive_comma = 0
        total_positive_comma = 0
        comma_id = tag_vocab[","]

        # get predictions
        predictions = self.predict_all(test_iter)
        assert len(predictions) == len(test_iter)

        # generate counts
        for batch_tag_pred, batch in zip(predictions, test_iter):
            for tag_ids_pred, example_tag_ids in zip(batch_tag_pred, batch["
                assert len(tag_ids_pred) == len(example_tag_ids)
                for tag_id_pred, tag_id in zip(tag_ids_pred, example_tag_ids
                    tag_id = tag_id.item()
                    total += 1
                    if tag_id_pred == tag_id:
                        correct += 1
                    if tag_id_pred == comma_id:
                        predicted_positive_comma += 1  # predicted positive
                    if tag_id == comma_id:
                        total_positive_comma += 1  # gold label positive
                    if tag_id_pred == comma_id and tag_id == comma_id:
                        true_positive_comma += 1  # true positive
        precision_comma = true_positive_comma / predicted_positive_comma
        recall_comma = true_positive_comma / total_positive_comma
        F1_comma = 2.0 / (1.0 / precision_comma + 1.0 / recall_comma)
        return correct / total, precision_comma, recall_comma, F1_comma
```

Now, we can train our baseline on training data.

In [ ]:
```
maj_tagger = MajorityTagger()
maj_tagger.train_all(train_iter)
```

Let's take a look at an example prediction using this simple baseline.

In [ ]:
```
# Get all predictions
predictions = maj_tagger.predict_all(test_iter)

# Pick one example
example_id = 2 # the third example
example = test_data[example_id]
prediction = predictions[example_id][0]

print('Ground truth punctuation:')
print(restore_punctuation(example['input_ids'], example['tag_ids']), '\n')
print('Predicted punctuation:')
print(restore_punctuation(example['input_ids'], prediction))
```

This baseline model clearly grossly underpunctuates. It predicts the tag to be `O` almost all of the time.

We can quantitatively evaluate the performance of the majority labeling tagger, which establishes a baseline that any reasonable model should outperform.

In [ ]:
```
accuracy, precision_comma, recall_comma, F1_comma = maj_tagger.evaluate(test
print (f"Overall Accuracy: {accuracy:.4f}. \n"
       f"Comma: Precision: {precision_comma:.4f}. Recall: {recall_comma:.4f}
```

Question: You can see that even though the overall accuracy is pretty high, the F-1 score for commas is very low. Why?

Type your answer here, replacing this text.

RNN Sequence Tagging

Now we get to the real point, using an RNN model for sequence tagging.

We provide a base class `RNNBaseTagger` below, which implements training and evaluation.

In [ ]:
```
class RNNBaseTagger(nn.Module):
    def __init__(self):
        super().__init__()
        self.N = ...    # tag vocab size provided by subclass
        self.Vo = ...   # text vocab size provided by subclass

```

You will implement the forward pass of an RNN from scratch. **You should implement the `forward` function from scratch and *not* use `nn.RNN`**. We'll make use of this convenient PyTorch module in the next part.

Recall that

$$h_0 = 0 \tag{1}$$
$$h_t = \sigma(\vect{U} x_t + \vect{V} h_{t-1} + b_h) \tag{2}$$
$$o_t = \vect{W} h_t + b_o \tag{3}$$

where we embed each word and use its embedding as x_t, and we use o_t as the output logits. (Again, the final softmax has been absorbed into the loss function so you don't need to implement that.) Note that we added bias vectors b_h and b_o in this lab since we are training very small models. (In large models, having a bias vector matters a lot less.)

You will need to implement both the `forward` function and the `predict` function.

> **Hint:** You might find `torch.stack` useful for stacking a list of tensors to form a single tensor. You can also use `torch.mv` or `@` for matrix-vector multiplication, `torch.mm` or `@` for matrix-matrix multiplication.

> **Warning:** *Training this takes a little while, likely around three minutes for the full set of epochs. You might want to set the number of epochs to a small number (1?) until your code is running well. You should also feel free to move ahead to the next parts while earlier parts are running.*

Did your model outperform the baseline? Don't be surprised if it doesn't: the model is very small and the dataset is small as well.

Lab debrief

Question: We're interested in any thoughts you have about this lab so that we can improve this lab for later years, and to inform later labs for this year. Please list any issues that arose or comments you have to improve the lab. Useful things to comment on include the following, but you're not restricted to these:

- Was the lab too long or too short?
- Were the readings appropriate for the lab?

- Was it clear (at least after you completed the lab) what the points of the exercises were?
- Are there additions or changes you think would make the lab better?

Type your answer here, replacing this text.

End of lab 2-2-a {-}

To double-check your work, the cell below will rerun all of the autograder tests.
